Abstract

Experiment was conducted at Agricultural Research Farm Malakandher, NWFP Agricultural University, Peshawar during the 2000/2001 season using Randomized Complete Block (RCB) design with four replications. The Canola Variety Dunkled was planted in plots of 6x3 m² during the last week of October, 2000. Data were recorded on weed density m⁻², days to 50% flowering, 1000 seed weight (g) and seed yield (kg ha⁻¹). The data recorded for each trait was individually from plots treated with Treflan 4EC applied pre-emergence. All the parameters were significantly affected by different herbicidal treatments. Minimum weed density (3.20 m⁻²) and the highest 1000 seed weight (3.68 g) and seed yield (1568 kg ha⁻¹) were recorded from plots treated with Treflan 4EC applied pre-emergence.

Key words: Canola, weeds and herbicides

Introduction

Rapeseed and mustard are grown in rabi season in irrigated and barani areas of Sindh, Punjab and North West Frontier Province (NWFP) of Pakistan. Rapeseed and mustard have remained one of the major sources of edible oil in the sub-continent and China for centuries. Their cultivation goes back to 2000-1500 B.C in the sub-continent as indicated by sanskrit content. Moreover, some genotypes of Indian mustard (B. juncea) are extremely low in erucic acid and glucosinolate content (A. Rabbani, NARC, Islamabad, Personal Communication). Canola has been recently introduced to Pakistan to increase domestic edible oil production. It is a rich source of oil and protein (5).

One of the main reasons for low acreage of Brassica spp. is that its sowing season overlaps with that of wheat. As wheat is the staple food of the nation, lesser attention is devoted to oilseed crops of rabi season. Brassica is mostly grown on barani lands and no improved practices are applied for this crop as most of the farmers are involved in wheat crop.

Canola is a smother crop, because of its larger leaves, rapid growth and early closing canopies, yet the weed competition is critical during early stand establishment. The very small size of canola seeds makes the attempts to eliminate weed seed contamination extremely difficult. Thus, infested crop fetch lower prices in the market apart from quantitative losses. The most common weeds of canola are Cyperus rotundus, Avena fatua, Vicia sp., Phalaris minor, Sorghum helapense, Fumaria indica, Convolvulus arvensis, Anagallis arvensis, Lathyrus aphaca, Medicago denticulate and Powa anua.

Keeping in view the importance of different herbicides for controlling weeds in canola, the present experiment was carried out with the following objectives: (i) to find out the most suitable herbicide for weed control in canola; and (ii) to figure out the effect of different herbicides on yield and yield components of canola.

Materials and Methods

The experiment was conducted at Malakandher Research Farm, NWFP Agricultural University, Peshawar during rabi season 2000/2001. Dunkled variety of canola, as availed from the Directorate of Oilseeds, Agricultural Research Institute, Tarnab, was planted on 28 October 2000. The seed rate used was 5kg ha⁻¹.

The experiment was laid out in a Randomized Complete Block (RCB) design with four replications. There were 10 treatments in each replication. The size of each plot was 6x3 m². Each treatment had 4 rows, 75 cm apart. The details of treatments during the study were the following:

Along weedy check Pre-emergence herbicides namely Treflan 4 EC, Dual Gold 960 EC, Stomp 330 EC and Sencor WP70 were used at the rate of 1.20, 1.44, 0.99 and 0.35 kg ai ha⁻¹, respectively. Post-emergence herbicides namely Ronstar 12 L, Fusilade 13 EC, Topik 15 Wp, Puma super 75 EW and Agil 100 EC were used at the rate of 0.36, 0.26, 0.03, 0.75 and 0.15 kg ai ha⁻¹, respectively.

These herbicides were applied with the help of Knapsack sprayer. The pre-emergence herbicides were applied before the emergence of crop, while the post-emergence herbicides were applied after the emergence of canola crop i.e. after 35 days

The following parameters were recorded during the course of experiment: 1) Weeds' density m⁻² (before and after application of post-emergence herbicides), 2) Days to 50% flowering, 3) 1000 seed weight (g), and 4) Seed yield (kg ha⁻¹). The data recorded for each trait was individually
subjected to the ANOVA Technique by using MSTATC computer software and means were separated by using Fisher’s Protected LSD test (4).

Results and Discussion

Weeds density m²
The data regarding weeds density m² is presented in Table 1. The maximum weeds m² (18.83) were recorded in the weedy check. Minimum weed densities were recorded in Treflan 4 EC (3.20 m²) and Fusilade 13 EC (4.77 m²) treated plots. The variability in weeds population in different treatments can be attributed to the fact that some herbicides are more effective for weed control than the others. The results are in conformity with those reported by Khan et al. (1) who stated that Treflan 4 EC at the rate of 1-2 liters ha⁻¹ in rapeseed and at the rate of 1-1.5 liters ha⁻¹ in mustard was the best treatment, significantly reducing the weed density and dry weight.

Days to 50% flowering
Data on the effect of different herbicides on days to 50% flowering are also presented in Table 1. The comparison of the mean values indicated that maximum days (129.8) to 50% flowering were recorded in the plots receiving Sencor WP70 treatment while minimum (119.8) days to 50% flowering were recorded in plots treated with Ronstar 12 L herbicide. This rapid flowering in Ronstar-treated plots was, however, statistically not different from many other treatments., as well as, the weedy check (120.5 days). The possible reason for delay in flowering in Sencor WP70 plots might be the injury caused by its phytotoxic effect which was observed during the experiment.

Table 1 shows the effect of different herbicides on the grain yield. The data indicated that maximum grain yield was produced from plots treated to Treflan 4 EC (1568 kg ha⁻¹) and Fusilade 13 EC (1458 kg ha⁻¹). The Fusilade 13 EC was in turn statistically similar to Ronstar 12 L (1346 kg ha⁻¹), Topik 15 WP (1365 kg ha⁻¹), Puma Super 75 EW (1376 kg ha⁻¹) and Agil 100 EC (1341 kg ha⁻¹). Minimum grain yield of 1077 and 1155 kg ha⁻¹ was obtained in Sencor WP70 treated and weedy check plots, respectively. The perusal of data in Table-5 further revealed that the lowest 1000 seed weight (2.72 g) was obtained from Sencor WP 70 treated plots which was statistically equal (2.78 g) to the weedy check plots, which in turn was statistically at par with the remaining herbicidal treatments except the top scoring treatments and the Ronstar 12 L (3.20 g). The reason for lower seed weight in the Sencor WP70 treated plots might be the injury caused by Sencor WP70 during the experiment while 1000 seed weight increased with application of some herbicides which effectively controlled weeds. These results are in conformity with those reported by Raghavan and Hariharan (2) and Yadav et al. (7) who stated that seed weight increases with the application of some herbicides.

Grain yield (kg ha⁻¹)
Table 1 shows the effect of different herbicides on the grain yield. The data indicated that maximum grain yield was produced from plots treated to Treflan 4 EC (1568 kg ha⁻¹) and Fusilade 13 EC (1458 kg ha⁻¹). The Fusilade 13 EC was in turn statistically similar to Ronstar 12 L (1346 kg ha⁻¹), Topik 15 WP (1365 kg ha⁻¹), Puma Super 75 EW (1376 kg ha⁻¹) and Agil 100 EC (1341 kg ha⁻¹). Minimum grain yield of 1077 and 1155 kg ha⁻¹ was obtained in Sencor WP70 treated and weedy check plots, respectively. Grain yield significantly increased with the application of Treflan 4EC herbicide and these findings are in conformity with those reported by Khan et al. (1) who stated that the application of Treflan 4 EC at the rate of 1-2 liters ha⁻¹ in rape seed and at the rate of 1-1.5 liters ha⁻¹ in mustard significantly increased the grain yield. The minimum grain yield for Sencor WP70 treated plots is due to the inhibitory effect of Sencor WP70. Sharma and Mishra (3) have also reported phytotoxicity on crop due to some herbicides in their studies on rapeseed.
الملخص

تم تصميم هذه التجربة تجربة بشكل عشوائي، خلال موسم الزراعي 2000/2001 باستخدام تقسيم القطاعات
